SUMMARY
The techniques used to determine the condition of pressure water mains are briefly described and evaluated. Techniques are broadly categorised into two classifications – direct and indirect, with direct techniques being further subdivided into Intrusive and Non-Intrusive, depending on whether they cause disruption to the operation of the main. Indirect techniques are subdivided into Environmental and Operational Performance categories.
Condition assessment is seen as a staged approach, utilising many techniques, including the cost-effective Linear Polarisation Resistance (LPR) electrochemical technique, in conjunction with statistical and predictive modelling.

Keywords: Condition assessment of pressure water mains, Intrusive and non intrusive testing, Remote Field Technique
